ABSTRACT: Perineal scar endometriosis remains a rare diagnosis till date. We report a case of chronic scar endometriosis, where provisional diagnosis was established prior to surgery by high level of clinical suspicion. Our patient presented with perineal pain from ten years associated with severe superficial dyspareunia. Clinical examination revealed very tender 2-3 nodules at old episiotomy scar area with fibrosis. Complete deep triangular excision was performed and tissue sent for histopathology. A special request to look for endometriosis with CD4 cells was made, which confirmed the diagnosis. Postoperative period was uneventful and patient was kept on oral progesterone for 3 months without recurrence and her follow up is pain free till date.We feel the chief learning point is increased awareness and high clinical suspicion further leading to complete treatment.
